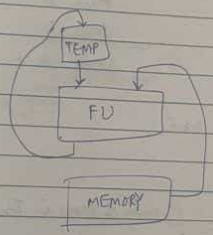
SUB B



(Intel)

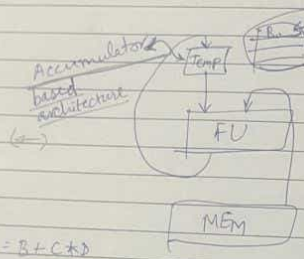
(← was PUSH, POP)

LOAD
STORE

A = B + C
LOAD B
ADD C
STORE A

Lec 15-3-22

ISA



A = B + C * D

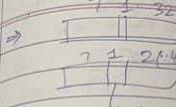
LOAD C
MUL D
ADD B
STORE A

A = B * C + D * E
LOAD B
MUL C
STORE T1 (∵ only 1 space in Temp (accumulator))
LOAD D — in main memory.
MUL E
ADD T1
STORE A

Accumulator is
STILL the bottleneck

↓

e.g. (A) = B + C
D = (A) + E — used multiple times → Store A in some registers
P = (A) + R

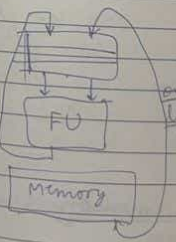


Addressing mode A/M (whether in memory, or registers)

LOAD B	40	7 + 1 + 32
ADD C	40	
STORE R0	10	7 + 1 + 2
LOAD E	40	
ADD R0	10	
STORE D		

→ ∴ no need of making memory reference

e.g. MUL C :
1800 ⇒ get the instr
+ 1000 ⇒ get C
+ 10 ⇒ do the operation
2010 cycles



3 address — | oper | op1 | op2 | dest | = 7 + 2 + 2 + 2 = 13 bit

Load Store : | oper | op1 | op2 | = 7 + 2 + 32
op1 → registers, op2 → memory
In Load, register ← mem, in Store : reg → mem (given addresses)

ISA

Constraints

1. Limited Memory : minimize #bits
2. Slow memory : complex instrⁿ
3. Ease of Programming

```
for ( i=0; i<1000; i++)
    A(i) = B(i) + C(i);
```

A(0) = B(0) + C(0);

⋮

A(999) = .. + .. ;

Can use (ptr.s to addresses) (& store these in registers)

R1 = 5000
R2 = 9000
R3 = 1000

ADD R1, R2, R3 , i.e. add things whose addresses are contents of R_1, R_2 & store at locⁿ with address = content of R3

M[R_3] = M[R_1] + M[R_2]

⇒ Operⁿ | opr1 | opr2 | Dest.

A/M (Addr-ing mode) →
1. Direct Memory
2. Register direct (content = opr.)
3. Register indirect (i.e. address of opr given)
4. Base + Offset (S.T)

Page No. 181

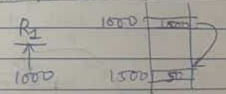
Next iterⁿ :
5004 (∵ 1 operand : 4 bytes)
9004
1004 (∵ *pointers)

A[10] addr. M1 is A + 40 (#bytes) ((R1), 40) offset

4. Base + Offset (~const.)

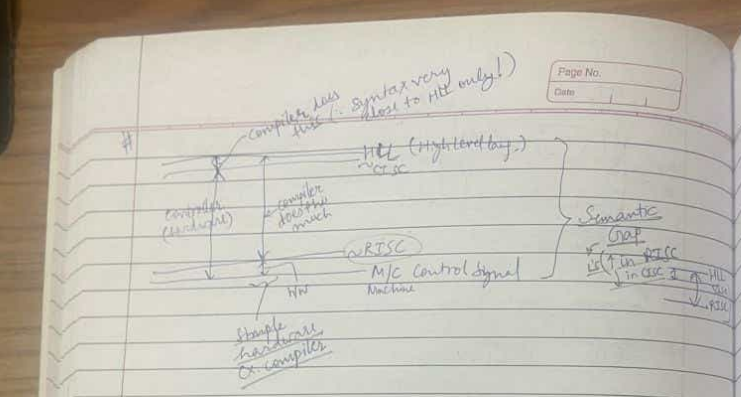
5. Base + Index (2× log(total registers))
i in another register } 2 registers
one R1 (base addr. (A))
other R5 (i)
[R1|R5] ← OPR1 की जगह.

6. Double ptr.
(a/vs:) → MEMORY INDIRECT



7. AUTO INCREMENT / DECREMENT

e.g.
PUSH R1, R2 (contains address of top of stack)
⇕
M(R2) = R1
R2 = R2 + 1 } ← automatically by AUTO INC (ptr. of top of stack incremented..)



- Only LOAD, STORE can access memory

- ADD A, B, C
  C = A + B — CX. Instⁿ
  LOAD R1, A
  " R2, B
  ADD R1, R2, R3
  STORE R3, C
  (2) — μ-ops. (micro-operᵃˢ)

- Why -O3 not used all the time in gcc?
  ↳ coz time↑ for compilⁿ
  ↑ runtime ↓ (from optimal code)

(a, b: always 1) (∵ 1 has to go to D_3) (h, i: no data mem in R) (J: uncond^nal)

Fill table & use K-maps on col^n s to get ckt for control vars (comb^nal logic).

- CPI = 1 (every instr^n: 1 cycle). (single go: can see ↑)

$\frac{\text{Time}}{\text{Prog}} = IC \times CPI \times T$
(IC: Dynamic count; CPI: 1)

Mem read / write : 2ns
RF " " : 1 ns
ALU : 2ns

- Longest path: load instr^n

2ns + 1 + 2 (ALU) + 2 + 1 (write RF) (assume MUXes time ≈ 0)
→ 8ns (max)
Freq of oper^n = $\frac{1}{8ns}$ = 125MHz

- for (i=0; i<1000; i++)
A(i) = A(i) + 1

} Static count of instr^n s = 1
Dynamic " " = 1000

↑ways S→S' (∵ single cycle: ✓, e.g. ↑ load..)
Can do S→P→P'→P''→S' too.
↳ Trans^n system.
↳ Sub-tasks
1. Instr^n Fetch
2. Update PC
} 'housekeeping' tasks (have to do)
3. Operand read
4. Instr^n Comput^n or Comput^n of addr. of memory
5. Read/Write Memory
6. Update the state (write to RF).

For A&L Instr
1. Instr^n fetch
2. Update PC
3. Opr. read
4. Instr^n Comput^n (read/write mem: ∅)
5. Write back to RF.

States

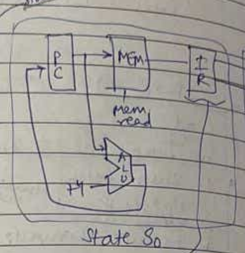
R-type (AL) Arithlog

1. Fetch instrⁿ
2. Update PC
3. Read operand
4. Execute
5. Write back result

State S_0

PC ⟶ Mem. add., alu-A	ADD
Mem. Data ⟶ I. Reg. (Instrⁿ Reg.)	S0
+4 → alu-B	S1
alu C ⟶ PC	

(addr. of instrⁿ to be fetched from mem.) — ALU operⁿ — state ID — next state ID



Instrⁿ in this form

31–26	25–21	20–16	15–11		5–0
OPERⁿ	OPR2	OPR1	Destⁿ		Func
6	5	5	5		6 bits

State S_1

IR_{25-21} ⟶ RF_A_1
IR_{20-16} ⟶ RF_A2
RF-D1 ⟶ T1
RF-D2 ⟶ T2

temp reg.s (can't reuse IR here ∵ use later. operⁿ, destⁿ)

S_2

T1 ⟶ Alu_A	OP
T2 ⟶ alu-B	S2
aluC ⟶ T3	S3

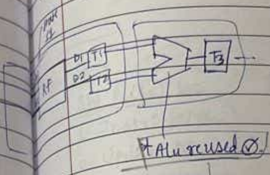
(tho can reuse T1 or T2 ...)
(NOT IR because operⁿ field req...) (see Next state) also (Destⁿ)

S_3

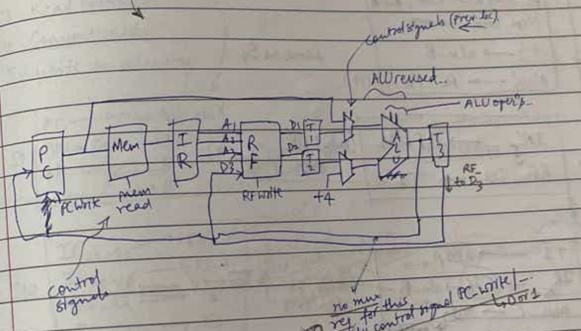
T_3 ⟶ RF_D_3 (to be written...)
IR_{15-11} → RF_A3 (Destⁿ...)

(this is why ... reuse)

$S_0 \longrightarrow S_1 \longrightarrow S_2 \longrightarrow S_3$



ALU reused ⊘.

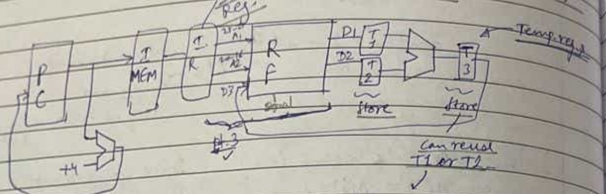


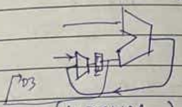
(R-type)

- Can do non-major tasks ||ly (∵ otherwise time ↑..)
  e.g. 1. & 2.
  ↳ ||

No Instrⁿ

* ∄ need of IR now
* VS: single go में सब हो..
but here, need to store it for next cycle ∅.





Apt: don't actually need this ALU ... bcoz at this state/cycle the later ALU is free..

Branch: BEQ R_{s1}, R_{s2}, Imm

I-type	Operⁿ	OPR 1	Destⁿ	IMM 16
	31 – 26	25 – 21	20 – 16 (~OPR2)	15 – 0

if (R_{s1} == R_{s2}) then
  PC = PC + 4 + Imm16 × 4
  * ∵ Imm16 is #instrⁿs (BEQ, J) (* 200 top : ~ (?))

Else
  PC = PC + 4

1. Fetch instrⁿ } "housekeeping" tasks
2. Update PC
3. Read operands (R_{s1} & R_{s2})
4. Compare (subtraction)
5. If zero then PC = PC + 4 + Imm16 × 4

A, B → ALU → C, zero (flag set if zero result)

S13:
- PC → mem_Addr, alu_A
- +4 → alu_B
- alu_C → PC
- Mem. Data → IR (i.e. instrⁿ fetched from memory, put into IR)

↓

S14:
- IR_{25-21} → RF_A1
- IR_{20-16} → RF_A2
- RF_D1 → T1 (temp. reg.)
- RF_D2 → T2
- PC → alu_A
- IR_{15-0} → SE_{16} → 2S → alu_B
- alu_C → T3

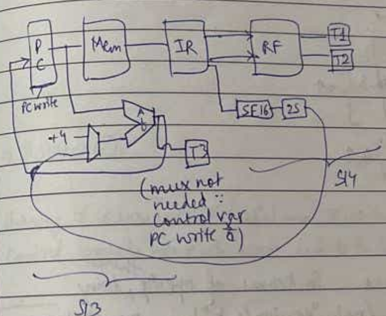
~ loaded in S13...

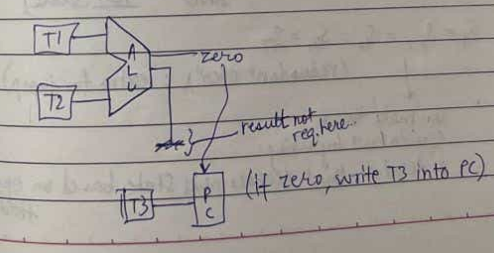
S15:
- T1 → alu_A } for subtrⁿ
- T2 → alu_B
- PC → alu2_A
- IR_{15-0} → SE16 → 2S → alu2_B
- if (zero == 1) then
  alu2_C → PC
  → T3

4 pt. 4, 5 can do ~ ∥ bcoz PC+4 +Imm16×4 computed first, then if zero → load into PC (otherwise nothing) — just PC ← PC+4

Aim: minimize #states so that CPI ↓.
& here: 2 ALUs req...
BUT can do alu2 tasks in S14 itself !!
Optimized in pencil. (PC pre-computed)

$S_{13} \rightarrow S_{14} \rightarrow S_{15}$. & only 1 alu
& " " memory } vs in single cycle 2 mems & 3 ALUs.





Jump instrⁿ : J-type format.

operⁿ	IMM26

1. Fetch instrⁿ
2. Update PC ← PC+4
3. Compute PC+4+Imm26×4
4. Update PC

(no "Read OPR" here, ofc)

(∵ when fetching instrⁿ, don't know which instrⁿ it is... ∴ ‖ they're ∴.)

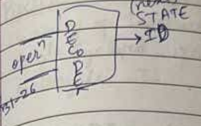
S16
- PC → Mem Addr, alu-A
- +4 → alu-B
- alu-C → PC
- Mem. Data → IR

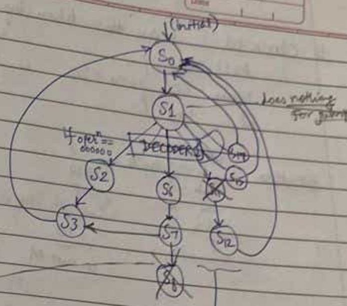
↓

S17
- PC → alu-A
- IR_{25-0} → SE26 (sign extend 26 bit) → 32 bit → 2S → alu-B } 3.↑
- alu-C → PC } 4.↑

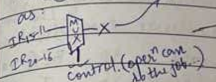
S0, S_4, S_9, S13, S_{16} same: in terms of operⁿs they're doing.
(not "equivalent", bcoz next states not same).

Can make $S_1 = S_5 = S_{10} = S_{14} = S_{17}$
(redundant operⁿs ; extra for jump)
↓
Can make these equivalent by using a decoder, that decodes next state based on operⁿ field.

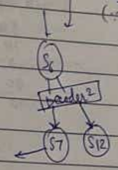




Can combine S_3, S_8 ✓ tho $IR_{(\ )}$ → diff : IR_X
as:



Can combine S_6, S_{11} if we use another decoder... (∵ NOT equivalent, but operⁿs same.)



⇒ 9 states ∅.

- Sharing of resources ✓ (add'al mem, ALU ⊗, but regs T₁... ∅)
- Control signals for each state need to be decided.

(↑ ~ assembly line)

	IF	ID	EX	MEM	WB
cycle 1:	I_1				
2	I_2	I_1			
3	I_3	I_2	I_1		
4	I_4	I_3	I_2	I_1	
5	I_5	4	3	2	1
6	6	5	4	3	2

LATENCY

(assuming independent instr^{n}s & not data-dep... (no control flows..)

after 5 cycles, 1 instr^n out every cycle ; so, looks like every instr^n in 1 cycle !!

$\Rightarrow$ CPI = 1

& T also ↓ because all "stages" doing work for different instructions

$\Rightarrow$ ~ multicycle ↓ T

$\Rightarrow$ T = 2ns.

$\Rightarrow$ IC × CPI × T ~ 4 times improvement

Hw to detect..

① Data Dependency

I_1 : $r_1 = r_2 + r_3$

I_2 : $r_4 = r_1 + r_5$ dependency

r_1 10
r_2 20
r_3 30
r_4 40
r_5 50

Characteristics of pipeline :

1. fetches 1 instr^n at a time
2. Unified pipelines
3. Lock step advancement (can't advance until all advances)

	IF	ID	EX	MEM	WB
I_3	(I_2)	I_1			

gets I_1 = 50 ← 20+30 = 50 computed & stored in pipeline register (EX/MEM)

if dest^n of I_1 = src of I_2, then problem

↳ if R^{ID}_{s1} == R^{EX}_{d} or R^{ID}_{s2} == R^{EX}_{d} (source 1, 2)

if so, do :

I_3	I_2	I_1		
I_3	I_2	–	I_1	
I_3	I_2	–	–	I_1 (written back)
I_3	I_2	–	–	–
I_4	I_3	I_2	–	–

3 cycles ~ wasted on such dependency. (∵ 3 cycles : movement ↓↑ ⊗)

eg. 10% dep ⇒ $1 \times 0.9 + 3 \times 0.1 = 1.2$ (CPI)

penalty for 10%

⇒ Can do : read from pipelined reg. ("50" EX/MEM)

↳ k/a Data fwd-ing / Data bypassing.

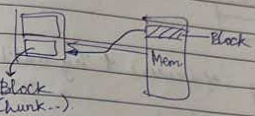
3rd " : 1+1, 1+1 } 2
⋮ } 2
⋮

$CPI = \frac{201 + 201 + 2 + \ldots + 2}{2000}$ (# instrⁿs) $= \frac{402 + 2\times998}{2000}$

$= \frac{398 + 4 + 2\times998}{2000}$

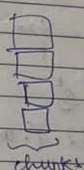
$= \frac{2398}{2000} \sim 1.2$ (close to 1)

⇒ bring instrⁿs b/w 2 branches



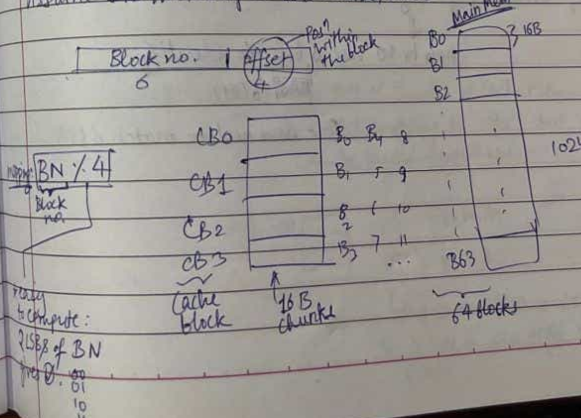
32kB cache mem.

Questions ↑ :



1. Where to place?
2. How to identify? — b/c I_{21} etc. & memory address
3. Whom to evict?
4. How to handle write? (∵ data in cache, memory)

Assume 1024B memory & 16B blocks



these bits give CB#

To identify e.g. B_1, B_5, B_9 (i.e. same CB#)
⇓
maintain TAG bits
(MSB of [6 | 4])

TAG
D E C O D E R → 0000 → B1, 0001 → B5, ... (MSB 4 bits)

Indexing delay (of decoder) + Tag match delay +.

2 bits only (∵ 4 chunks)

but

e.g. $I_0 - I_1$ → B_1; $I_{20} - I_{21}$ → B_9 (example)

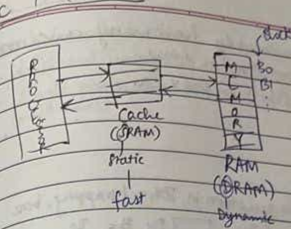
~~same chunk~~ ← → performance ↓↓. (∵ will kick out the other). 1 iter, bring B_1, next, bring B_9...

So, allow to go anywhere in the 4 chunks
⇓
now hv to use 6 bits to identify
[TAG] (6 bits).

But now need to match 6 bits...

Lec 7-4-22

Page No. 231



4 questions 229

① M1 (set") Direct Mapping

Problem: e.g. for (____)
if (i%2 == 0)
B1 — {I_0; ...
else I_{20}; ...
{B9

then after every iter CB1 content replaced.

M2: e.g. 4GB RAM, 64B Blocks, 32 KB cache → 512 things to compare in ||.
"Fully Associative"

⇓

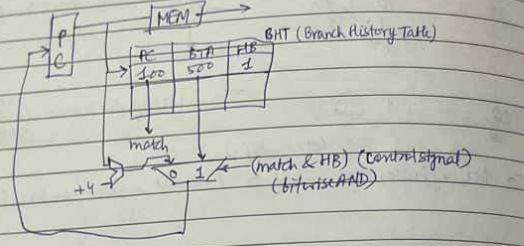
M3: Middle Way: make sets of chunks of Cache Mem.
& direct mapping to sets, but inside set, can be placed anywhere.

SET ASSOCIATIVE MAPPING (most common used)

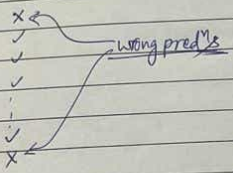
e.g. CB 0, 1, 2, 3 → S0 {B0, B2, B4, ...; S1 {B1, B3, B5, ...
↳ 1 bit req. (LSB = %2)
& 5 bits to identify within set.
(TAG)

Lec 6-4-22

Branch Predictor

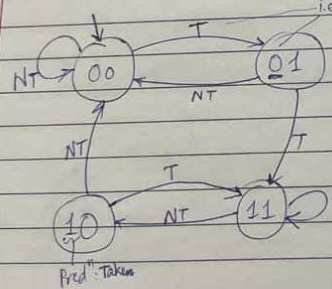


e.g. of loop



⇒ use 2 Bits (History)

00 ↑ use MSB for pred" (0: NT, 1: T) — not taken, taken



⇒ Now only 1 wrong decision (at exit)
(1st time of all: 3 wrong decisions — then only 1 wrong per loop...)

2 bits: 3 + 999×1 out of 1000×1000 → 85-90% accuracy
Single bit: ~80-85%.

Example: α [Ir" / B], 90% accuracy
↳ Ø pred" → no loss in → I_1 I_2 I_3
Ø " → 2 cycles' loss

$CPI = 1 + \alpha \times \frac{1}{10} \times 2$
$= (1 + 0.2\alpha)$ if $\alpha = 0.2$ → $1 + 0.04$
$= 1.04$

Correlation b/w branches

Example:
if (i%2 == 0) then... → if NT, then NT Ø (pred")
if (i == j) then...
if (i%10 == 0)...

[e.g. BI MOD predictor 2 level]

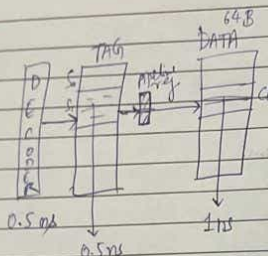
(↙ 2bit branch predictor considering all branches as independent)

I_1: $r_1 = r_2 + r_3$
I_2: beq r_4, r_5, skip
I_3: $r_7 = r_8 + r_9$

skip: $r_3 = r_4 + r_7$
I_{20}

Can put a rule in ISA: an instr" is always executed after branch.
↓
can do: reshuffle I_2 ... I_1 ...
must be indep of branch
↓
1 cycle saved

Even if $h = 100\%$ (hit rate), then CPI ~ 1.15
data dep., control flow



$t_{dec} + t_{tag} + t_{data}$
2 ns
2 cycles for 1 GHz

Pipelined Caches

IF1 — IF2 — ID — EX — MEM1 — MEM2 — WB

$IPC = \frac{1}{CPI}$
Instr's per cycle

CPI ≈ 1 (1.3/1.4) for pipelined

* can pick instr's from multiple src.s ⇒ ~independent

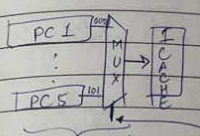
	IF	ID	EX	MEM	WB
src of this instr	I_1^1				
	I_1^2	I_1^1			
	I_1^3	I_1^2	I_1^1		
	I_1^4	I_1^3	I_1^2	I_1^1	
	I_1^5	I_1^4	I_1^3	I_1^2	I_1^1
	I_2^1	.	.	.	~out

all src.s diff. (+80 control flow, branching etc.) ⇒ no problem).
- No data dep.

✓ CPI = 5 for each src.
But combined, CPI = 1

Context (each process has a)
1. Memory (Core segment / Data segment / Stack segment)
2. RF
3. PC
4. Files

Need multiple PC's

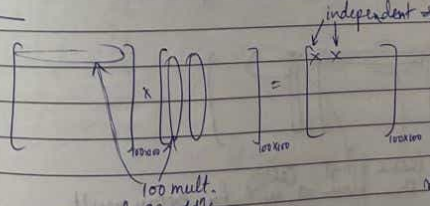


for fetching from different sources.

modulo 5 counter will work ✓ (FSM)

& multiple RF's

e.g.



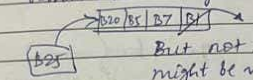
independent ⇒ can do concurrently
⇓
make multiple threads & then run them concur. as.
⇓
need diff. SS, RF, PC

#Blocks in a set : determined by how many concurrent matches can be done...
e.g. 5 bits in prev ex.

Qs 1, 2 done

Q3. Whom to evict? [no question in Direct Mapping, bcoz e.g. [ ] B1 B5 B9... ⇒ kick out existing.]

- can do: remove blocks by FIFO



But not an efficient M, bcoz B1 might be used...

- LRU: Least recently used

e.g. 
Now B5 used ⇒ do 
then B1 ⇒ 
then B21 ⇒ 
then :

hv to maintain queues for each set (for set associative mapping)

hv to do lot of work

⇓

approximate : FIFO BUT NOT MRU

Q4. How to handle writes:
- ~~different~~ images in cache & memory
- single processor ⇒ first see if not in cache. If hit ⇒ use that. Else miss ⇒ use from memory
(multi-how?)

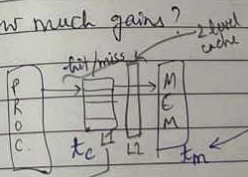
↳ to signify that a CB is modified ⇒ maintain 1 bit

- if modified, then if evicting, write back to memory...
↳ this can use a temp. loc^n & then write back from it (to save time)

Write-back policy

- Write-Through policy
↳ while modifying cache ⇒ write into memory too
(✓ also for multiple processors). ↑ but memory traffic ↑...
↳ while evicting, no dirty bit req....

How much gains?



hit rate : h (~90-95%)
miss " : $m = 1-h$

$t_A = t_c + m \cdot t_m$ (? regarding time?)

∵ always cache ① accessed ① first...

$= 1 + 0.1 \times 200 = 21$

Page No.
Date

for 2 level cache

$t_A = t_{L1} + m_1 t_{L2} + m_1 m_2 t_M$

$= 1 + 0.1 \times 10 + 0.01 \times 200$

$= \boxed{4}$

$(h_1 = h_2 = 0.9)$

10 cycles to access L2 cache

- 3-level cache

32 KB	512 KB	2MB
1	10	50

$\Downarrow \quad (h_i = 90\%) \; i = 1,2,3$

$CPI = t_{L1} + m_1 t_{L2} + m_1 m_2 t_{L3} + m_1 m_2 m_3 t_m$

$= 1 + 0.1 \times 10 + 0.1 \times 0.1 \times 50 + (0.1)^3 \times 200$

$= 1 + 1 + 0.5 + 0.2$

$= \boxed{2.7}$

(diminishing returns!)

Single cycle

Sec 11-4-21

1. Hierarchy of Memory

L1 – L2 – L3 – Main Mem.

32 KB | 256 KB | 2MB | 16GB

1-2 cycles | 10 cycles | 40 cycles | 150 cycles

$t_A = t_{L_1} + m_1 t_{L_2} + m_1 m_2 t_{L_3} + m_1 m_2 m_3 t_m$

3C-model

1. Compulsory Miss (cold start) (~ first time brought the block)
2. Capacity miss
3. Conflict miss — max in the direct mapping, min in fully assoc.

further capacity miss↑ (cannot afford large size cache)

IF ID EX MEM WB

(* Single cycle, Pipelined ✓ 2 mem. ✓)

* all in ∥ (on different I's)

P C → I. Mem

L1-I cache 32 KB

D. MEM

L1-D cache 32 KB

Tue. 12-4-22

Multiple RFs for : e.g. $R_1' = R_2' + R_3'$
and $R_4^2 = R_2^2 + R_3$

To improve CPI of individual srch, utilize
e.g. matrices.

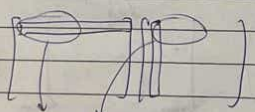
- Threads (theoretically, 10^2 ✓ for K) :: indep.
  - execute same instr's : 100 mult + 99 add's
  - ~~private~~ PC, ~~RAF~~, ~~STACK~~, Archi. RF
  - SIMD (for IF ID EX MEM WB)
  - gives CPI ~ 1 for the matrix ex.

Parallel Programming

e.g. for (i=0; i<1000; i++) → pthread
✓ A(i) = B(i) + C(i)
✗ A(i) = A(i-1) + B(i) → threads not indep.
(dependency)

- Logical cores (my: 2× Physical cores)
  - can provide indep. stream of instr's.

- Example:

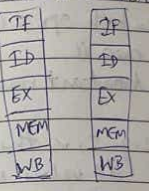


Cache brings this block ⇒ cache miss for every mult. (2nd matrix)

- so A·B ⇒ store B as B^T to prevent this.

- Graphs : CSR/CSC

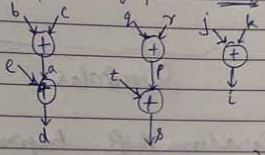
- To use CPI < 1 : Fetch multiple instr's at once (use multiple pipes)



✓ If indep. instr's
BUT ✗

- I_1 a = b + c
  I_2 d = a + e
  I_3 p = q + r
  I_4 s = p + t
  I_5 i = j + k

Data flow / Control graphs: DFG



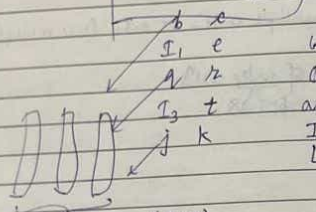
Theoretically, I_1, I_3, I_5 in ∥ → "1 cycle" (just theo.) → 2 cycles
Then I_2, I_4 " "

⇒ I_1
I_3
I_5
I_2
I_4

IPC = 5/2 = 2.5 (>1!)

To produce the DFG

Temp. Storage
e.g. d=@1 e
↳ tag, that I_1 will produce this



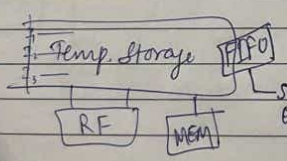
f'al pipes (II∅)

When both opr. & ✓ for any I_i, can exec. it, and broadcast result with tag I_i.
↳ e.g. I_1 ✓, then broadcast d's value with tag I_1,
⇓
I_2 too ready to be exec. ✓

Superscalar

- Paradigm shift: Program ~~exec~~ guided exec^n (PC,..)
to
Data guided exec^n.

- Issues :- debugging difficult. (∵ e.g. just a stmt hv been updated, but in 1 cycle, a, p, i updated)
⇓
- use temporary storage (e.g. don't write p, i into RFs (so that programmer can debug), but store in temp ✓)



so program order ✓

- SMT, P4 (Hyperthreading)
- can use different instr^n streams

Size, Associativity of caches.
